1 Math Theory: General Total Factor Productivity (TFP) Equation

The general form of the TFP can be measured as aggregate output (Y) divided by real total inputs (X). Rates of TFP growth are constructed using the Törnqvist index approach. The TFP growth over two time periods is defined as:

$$ln(TFP_t/TFP_{t-1}) = \sum_{i=1}^{n}((\frac{R_{i,t} + R_{i,t-1}}{2}) * ln(\frac{Y_{i,t}}{Y_{i,t-1}}))) - \sum_{j=1}^{m}((\frac{W_{j,t} + W_{j,t-1}}{2}) * ln(\frac{X_{j,t}}{X_{j,t-1}})))$$

Such that:

- Output $= \sum_{i=1}^{n}((\frac{R_{it}+R_{it-1}}{2}) * ln(\frac{Y_{it}}{Y_{it-1}}))$
- Input $= \sum_{j=1}^{n}((\frac{W_{jt}+W_{jt-1}}{2}) * ln(\frac{X_{jt}}{X_{jt-1}}))$

where:

- Y_i are individual outputs. This will later be refered to as Q_i in the following equations.
- X_j are individual inputs
- R_i are output revenue shares
- W_j are input cost shares
- t and $t-1$ are time subscripts, where 1 is the minimum year in the dataset
- i is category, e.g., Finfish (=1), Shellfish (=2)
- s is species, e.g., Salmon, Alewife, Surf Clams

---

2 Output Method: From Price to Quantity Measures

2.0.1 Variable Summary

Variables

- Q are individual quantity outputs in pounds (lbs).
- V are individual value outputs in dollars ($)
- R are output revenue shares
- P are prices
- PC are price changes
- PI are price indicies, often defined by a price from a base year *baseyr*
- *baseyr* is the year to base all indicides from

Inidicies

- t and $t-1$ are time subscripts, where 1 is the minimum year in the dataset
- i is category, e.g., Finfish (=1), Shellfish (=2)
- s is species, e.g., Salmon, Alewife, Surf Clams

2.0.2 Data requirements

We need time series data for the value of all species (V_t; e.g., Total), value of all species in a category (i) ($V_{i=1}$; e.g., Finfish), value of each species in a category (i) ($V_{i=1,s=n}$; e.g., Salmon and Summer Flounder), quanity of all species in a category (i) (in lbs, $Q_{i=1}$; e.g., Finfish and others), and the quantity of each species in a category (i) ($Q_{i=1,s=n}$; e.g., Salmon and Flounder):

2.0.2.1 Edit Data

Here we summate the category and total V because there may be instances where these values may not be the sum of their parts (though they are here). The caluclation Price Index aims to deal with this potiental issue.

```r
temp<-read.csv(file = paste0(dir.data, "Tornqvist Index-Calculations_OutputEx.csv"))
rownames(temp)<-temp$year
temp$year<-NULL

temp.q<-temp[,grepl(pattern = "Q", x = names(temp))]
temp.q$QE0_0Total<-rowSums(temp.q, na.rm = T)
temp.q$QE1_0Finfish<-rowSums(temp.q[,grepl(x = names(temp.q), pattern = "Q1") ], na.rm = T)
temp.q$QE2_0Shellfish<-rowSums(temp.q[,grepl(x = names(temp.q), pattern = "Q2") ], na.rm = T)

temp.v<-temp[,grepl(pattern = "V", x = names(temp))]
temp.v$V0_0Total<-rowSums(temp.v, na.rm = T)
temp.v$V1_0Finfish<-rowSums(temp.v[,grepl(x = names(temp.v), pattern = "V1") ], na.rm = T)
temp.v$V2_0Shellfish<-rowSums(temp.v[,grepl(x = names(temp.v), pattern = "V2") ], na.rm = T)

temp<-orgional.data<-cbind.data.frame(temp.q, temp.v)
```

2016	15	2200	100	160	NA	1100	3575	

2.0.2.2 The nameing conventions of the column names.

For example, in "V1_0Finfish":

- "V"... refers to the variable represented in the column (here V = "Value")
- ..."1"... refers to the category index (here, = Finfish)
- ..."_"... is simply a seperator in the title
- Since this is the total, ..."0".. refers to the index of the species, which is not relevant since this is the sum of the category, hense = 0
- ..."Finfish" is purely descriptive (here the name of the category), so you can follow along with what is happening!

Similarly for "Q2_2Clam":

- "Q"... refers to the variable represented in the column (here Q = "Quantity")
- ..."2"... refers to the category index (here, = Shellfish)
- ..."_"... is simply a seperator in the title
- ..."2".. refers to the index of the species, such that this organism happens to be the second species of this category.
- ..."Clams" is purely descriptive (here the name of the species), so you can follow along with what is happening!

We can do the structuring work in a function

This funciton standardizes the length of the category or species numbers e.g.,(numbers of 33, 440, and 1 are converted to 033, 440, and 001)

2.0.3 Lets get started

```
ii<-1 #The category index value
baseyr<-2010
PercentMissingThreshold<-0.50 #If data are missing by the below percentage, remove data
```

In most of the following examples, we will just focus on the finfish (i=1) side of the equation. Here *baseyr* is set to 2010 and the *PercentMissingThreshold* (The percent of data in a column that we will allow to be missing for analysis; more on that later) is set to 0.5%.

Here I am just going to do some housekeeping:

```
warnings.list<-list() #save issues we encounter in the code

NumberOfSpecies<-numbers0(x = c(0, strsplit(x =
                                              strsplit(x = names(temp)[1],
                                                       split = "_")[[1]][2],
                                            split = "[a-zA-Z]")[[1]][1]))[1]

NameBaseTotal<-substr(x = sort(names(temp)[grep(x = names(temp),
                                                  pattern = "0Total")], decreasing = T)[1],
                        start = 2, stop = nchar(sort(names(temp)[grep(x = names(temp),
                                                                  pattern = "0Total")],
                                                   decreasing = T)[1]))

VColumns<-grep(pattern = paste0("V", ii,"_"),
                 x = substr(x = names(temp),
                            start = 1,
                            stop = (2+nchar(ii))))

NameBasecategory<-substr(start = 2,
                           stop = nchar(names(temp)[VColumns[(grepl(
                             pattern = paste0("V", ii,"_",
                                              numbers0(x = c(0, length(VColumns)-1))[1]),
                             x = names(temp)[VColumns]))]]),
                           x = names(temp)[VColumns[(grepl(
                             pattern = paste0("V", ii,"_",
                                              numbers0(x = c(0, length(VColumns)-1))[1]),
                             x = names(temp)[VColumns]))]])

VColumns<-VColumns[!(grepl(pattern = paste0("V", ii,"_",
                                            numbers0(x = c(0, length(VColumns)-1))[1]),
                           x = names(temp)[VColumns]))]
```

2.0.4 Remove any V and Q data where V column has less data than the specifed *percentmissingthreshold*

```
VColumns0<-VColumns
QColumns0<-QColumns<-which(names(temp) %in%
                             paste0("Q", substr(x = names(temp)[VColumns],
                                                start = 2,
                                                stop = nchar(names(temp)[VColumns]))))
for (i in 1:length(VColumns)) {

  #if the percent missing is less in V or Q columns for a species than the percentmissingtrheshold, we
  if (sum(is.na(temp[VColumns[i]]))/nrow(temp) > PercentMissingThreshold | #V
      sum(is.na(temp[QColumns[i]]))/nrow(temp) > PercentMissingThreshold ) {#Q

    names(temp)[VColumns[i]]<-paste0("REMOVED_", names(temp)[VColumns[i]])
    VColumns0<-VColumns0[!(VColumns0 %in% VColumns[i])]
    names(temp)[QColumns[i]]<-paste0("REMOVED_", names(temp)[QColumns[i]])
    QColumns0<-QColumns0[!(QColumns0 %in% QColumns[i])]
  }
}

VColumns<-names(temp)[VColumns0]
QColumns<-names(temp)[QColumns0]
```

	Q1_1Salmon	Q1_2Cod	Q2_1Shrimp	Q2_2Clam	REMOVED_Q1_3Flounder	Q1_4SeaBass

2016	15	2200	100	160	NA	1100

2.0.5 Caluclate Catagory Sums of V and Q

Because we removed some columns for not meeting a perecent missing threshold of 0.5% and those columns will not be used at all in any part of the further analysis, we need to re-calculate the totals of V and Q for the catagories and the fishery as a whole.

```
names(temp)[grep(pattern = NameBasecategory, x = names(temp))]<-
  paste0("REMOVED_",
         names(temp)[grep(pattern = NameBasecategory, x = names(temp))])

  # Q
  temp.q<-temp[,grepl(pattern = paste0("Q", ii), x = substr(names(temp), start = 1, stop = 2)) ]
  temp.q<-data.frame(temp.q)
  if (ncol(temp.q)>1) {
    temp.q<-rowSums(temp.q, na.rm = T)
  }
```

```
  temp[ncol(temp)+1]<-temp.q
  names(temp)[ncol(temp)]<-paste0("QE",NameBasecategory)

  # V
  temp.v<-temp[,grepl(pattern = paste0("V", ii), x = substr(names(temp), start = 1, stop = 2)) ]
  temp.v<-data.frame(temp.v)
  if (ncol(temp.v)>1) {
    temp.v<-rowSums(temp.v, na.rm = T)
  }
  temp[ncol(temp)+1]<-temp.v
  names(temp)[ncol(temp)]<-paste0("V",NameBasecategory)
```

2.0.6 Price for each species ($P_{s,i,t}$; e.g., Salmon and Flounder)

We first measure output price for each species in each of the categories (e.g., Finfish & Others and Shellfish) using detailed landings time series data on value ($) and pounds (lbs).

Price for a species (s) of category (i) in year (t) =

$$P_{s,i,t} = V_{s,i,t}/Q_{s,i,t}$$

where:

- $P_{s,i,t}$ is the price per individual species (s), category (i), for each year (t)
- $Q_{s,i,t}$ is the quantity (lb) per individual species (s), category (i), for each year (t)
- $V_{i,t}$ is the value ($) per category (i), for each year (t)

Here we calculate the price for each species

```
    # Find which columns in this table are price Columns - we will need this for later
    PColumns<-paste0("P", substr(x = VColumns,
                                start = 2,
                                stop = nchar(VColumns)))

#####Price for each species#####
tempP<-data.frame(data = rep_len(x = NA, length.out = nrow(temp)))
for (c in 1:length(VColumns)) {

    NameBase<-substr(start = 2,
                   stop = nchar(VColumns[c]),
```

```
                  x = VColumns[c])

    Q0<-temp[,names(temp) %in% paste0("Q", NameBase)]
    V0<-temp[,names(temp) %in% paste0("V", NameBase)] #to make sure its the same column
  tempP[,c]<-V0/Q0
  names(tempP)[c]<-paste0("P", NameBase ) #name the column
}

  tempP<-as.matrix(tempP)
  tempP[tempP %in% Inf]<-NA
  tempP<-data.frame(tempP)
  temp<-cbind.data.frame(temp, data.frame(tempP))
```

	P1_1Salmon	P1_2Cod	P1_4SeaBass
1	NA	1.400000	NA
2	NA	1.421053	0.1000000
3	NA	1.450000	0.1222222
4	5.00000	1.200000	NA
5	10.00000	1.291667	NA
6	12.50000	1.260870	NA
7	16.36364	1.400000	0.1000000
8	15.45455	1.391304	NA
9	20.00000	1.458333	NA
10	12.00000	1.454546	NA

There may be instances where price cannot (or should not) be calculated because there is no or too few Q or V data for that species in a year or ever. The next goal will be to calculate the price change, so we need to have a value in there that won't show change. If we left a 0 in the spot, then the price change from 0 to the next year would be huge and misrepresented on the index. To avoid this, we have to deal with four senarios:

2.0.6.1 1. If there are instances for a species where there are too few pairs of V and/or Q are completely missing from the timeseries or where a percent of V is missing from the timeseries, we will remove the offending price columns entierly, so they don't influence the downstream price change or price index calculations.

Let's say here that if 50% of the data is missing in a given $V_{s,i,t}$, don't calculate that species $P_{s,i,t}$

```
#Find which columns in this table are price Columns

cc<-c() #Empty
for (c in 1:length(VColumns)) {

  #If price could never be caluclated at any point in the timeseries (is 0/NaN/NA) for a column (c)
  #Remove the column from the analysis.
  #We will not be removing the column from the data, but simply remove it from the varaible "PColumns"
  if (#sum(temp[,PColumns[c]] %in% c(0, NA, NaN)) %in% nrow(temp) |
      sum(temp[,PColumns[c]] %in% c(0, NA, NaN))/nrow(temp) > PercentMissingThreshold) {
    cc<-c(cc, c)#Collect offending columns
  }

}
```

```
if (length(cc)>0){
  PColumns<-PColumns[-cc]
  # VColumns<-VColumns[-cc]
  # QColumns<-QColumns[-cc]
}
```

2015	20.00000	1.458333
2016	12.00000	1.454546

2.0.6.2 2. If the first value of $P_{i,t,s}$ is 0/NA in a timeseries, we let the next available non-zero/non-NA value of P in the timeseries inform the past.

$$where \begin{cases} if: P_{i,t=1}=0, then: P_{i,t=1}=P_{i,t=1+1...} \\ if: P_{i,t\neq 1}=0, then: P_{i,t}=P_{i,t-1} \end{cases}$$

We use this *ReplaceFirst* function:

```
print(ReplaceFirst)
```

```
## function(colnames, temp) {
##   for (c in 1:length(colnames)) {
##
##     #If the first value of the timeseries of this column (c) is 0/NaN/NA
##     #Change the first value (and subsequent 0/NaN/NA values) to the first available non-0/NaN/NA valu
##     if (temp[1,colnames[c]] %in% c(0, NA, NaN)) {
##       findfirstvalue<-temp[which(!(temp[,colnames[c]]  %in% c(0, NA, NaN))),
##                            colnames[c]][1]
##       temp[1,colnames[c]]<-findfirstvalue
##     }
##   }
##   return(temp)
## }
```

```
temp<-ReplaceFirst(colnames = PColumns, temp)
```

	P1_1Salmon	P1_2Cod
2007	5.00000	1.400000

2015	20.00000	1.458333
2016	12.00000	1.454546

2.0.6.3 3. If there is a value in the middle of $P_{i,t,s}$'s timeseries that is 0/NA, we let the most recent past available non-zero/non-NA of $P_{i,t,s}$ in the timeseries inform the future.

We use this *ReplaceMid* function:

```
print(ReplaceMid)
```

```
## function(colnames, temp) {
##   for (c in 1:length(colnames)) {
##     #If a middle value of the timeseries of this column (c) is 0/NaN/NA
##     #Change the currently 0/NaN/NA value to the previous available non-0/NaN/NA value
##     if (sum(temp[,colnames[c]] %in% c(0, NA, NaN))>0) {
##       troublenumber<-which(temp[,colnames[c]] %in% c(0, NA, NaN))
##       for (r in 1:length(troublenumber)){
##         findlastvalue<-temp[troublenumber[r]-1, colnames[c]][1]
##         temp[troublenumber[r],colnames[c]]<-findlastvalue
##       }
##     }
##   }
##   return(temp)
## }
```

```
temp<-ReplaceMid(colnames = PColumns, temp)
```

2016	180	3200

2.0.8 Value of species $VV_{i,t}$ where P was able to be calculated

$R_{i,t}$, as defined and discussed in the subsequent step, will need to sum to 1 across all species in a category. Therefore, you will need to sum a new total of $V_{i,t}$ available (called $VV_{i,t}$) for the category using only values for species that were used to calculate $P_{i,t}$ (called $V_{s,i,t,available}$).

$$VV_{i,t} = \sum_{s=1}^{n}(V_{s,i,t,available})$$

where:

- $VV_{i,t}$ is the new total of $V_{i,t}$ (called $VV_{i,t}$) for the category using only values for species that were used to calculate $P_{i,t}$
- $V_{s,i,t,available}$ are the $V_{s,i,t}$ where P were able to be calculated

```
temp0<-data.frame(temp[,names(temp) %in% VVColumns],
                  rowSums(temp[,names(temp) %in% VVColumns], na.rm = T))
names(temp0)[ncol(temp0)]<-paste0("VV",NameBasecategory)
```

```r
temp0<-data.frame(temp0)
temp[ncol(temp)+1]<-temp0[ncol(temp0)]

temp0 %>%
    knitr::kable(row.names = T, booktabs = T)
```

2014	170	3200	3370
2015	200	3500	3700
2016	180	3200	3380

2.0.9 Revenue Share for each species ($R_{s,i,t}$; e.g., Salmon and Flounder)

$$R_{s,i,t} = V_{s,i,t}/VV_{i,t}$$

where:

- $R_{s,i,t}$ is the revenue share per individual species (s), category (i), for each year (t)
- $V_{s,i,t}$ is the value ($) per individual species (s), category (i), for each year (t)

Here we divide $V_{s,i,t}$ by $VV_{i,t}$ because $VV_{i,t}$ only includes species used to calculate $V_{s,i,t}$ as per the above price calculations.

```r
tempR<-data.frame(data = rep_len(x = NA, length.out = nrow(temp)))
for (c in 1:length(PColumns)) {

  #for renaming the columns
    NameBase<-substr(start = 2,
                    stop = nchar(PColumns[c]),
                    x = PColumns[c])

  V<-(temp[,names(temp) %in% paste0("VV", NameBasecategory)])  # sum of V where P was calculated
  V0<-temp[,names(temp) %in% paste0("V", NameBase)] #V of species; to make sure its the same column
  tempR[,c]<-V0/V
  names(tempR)[c]<-paste0("R", NameBase ) #name the column
}

tempR<-data.frame(tempR)
temp<-cbind.data.frame(temp, tempR)
```

	R1_1Salmon	R1_2Cod
1	0.0344828	0.9655172
2	0.0357143	0.9642857
3	0.0333333	0.9666667
4	0.0322581	0.9677419

	R1_1Salmon	R1_2Cod
5	0.0312500	0.9687500
6	0.0491803	0.9508197
7	0.0604027	0.9395973
8	0.0504451	0.9495549
9	0.0540541	0.9459459
10	0.0532544	0.9467456

2.0.9.1 Analysis Warnings Checks

As an additional check, let's make sure that each row sums to 1.

	x
1	1
2	1
3	1
4	1
5	1
6	1
7	1
8	1
9	1
10	1

Is there a warning?

No warning.

2.0.10 Price Changes for each species ($PC_{s,i,t}$ aka $\Delta ln(P_{s,i,t})$; e.g., Salmon and Flounder)

$$PC_{i,t} = ln(\frac{P_{i,t}}{P_{i,t-1}}) = \sum_{s=1}^{n}([\frac{R_{s,i,t}+R_{s,i,t-1}}{2}]*[ln(\frac{P_{s,i,t}}{P_{s,i,t-1}}]) = \sum_{s=1}^{n}([\frac{R_{s,i,t}+R_{s,i,t-1}}{2}]*[ln(P_{s,i,t})-ln(P_{s,i,t-1})])$$

Such that:

category's (i) Price Change $= ln(\frac{P_{i,t}}{P_{i,t-1}})$

category's (i) Price Change for each species (s) $= \frac{R_{s,i,t}+R_{s,i,t-1}}{2}$

category's (i) Revenue Share for each species (s) $= ln(\frac{P_{s,i,t}}{P_{s,i,t-1}}$

We use this *PriceChange* function:

```
print(PriceChange)
```

```
## function(R0, P0) {
##   PC0<-rep_len(x = 0, length.out = length(P0))
##   for (t in 2:length(P0)) {
##     temp1<-((R0[t]+R0[t-1])/2)
##     temp2<-ln(P0[t]/P0[t-1])
##     PC0[t]<-temp1*temp2
##   }
##   return(PC0)
```

```
## }
```

But here we'll do it manually so you can follow along:

```r
#Find which columns in this table are price and revenue share columns
tempPC<-data.frame(data = rep_len(x = NA, length.out = nrow(temp)))
for (c in 1:length(PColumns)){
  #For nameing columns
    NameBase<-substr(start = 2,
                     stop = nchar(PColumns[c]),
                     x = PColumns[c])

  # Calculate
  P0<-temp[, names(temp) %in% paste0("P", NameBase)]
  R0<-temp[, names(temp) %in% paste0("R", NameBase)] #to make sure its the same column
  tempPC[,c]<-PriceChange(R0, P0)
  names(tempPC)[c]<-paste0("PC", NameBase ) #name the column
}

temp<-cbind.data.frame(temp, tempPC)
temp[ncol(temp)+1]<-rowSums(tempPC, na.rm = T)
names(temp)[ncol(temp)]<-paste0("PC", NameBasecategory)
```

For reference, here are the Price Changes for each species ($PC_{s,i,t}$):

	PC1_1Salmon	PC1_2Cod
2007	0.0000000	0.0000000
2008	0.0000000	0.0144018
2009	0.0000000	0.0194695
2010	0.0000000	-0.1830357
2011	0.0220102	0.0712743
2012	0.0089738	-0.0231613
2013	0.0147572	0.0989356
2014	-0.0031679	-0.0058852
2015	0.0134715	0.0445941
2016	-0.0274080	-0.0024612

And here is the summed ($\sum$) Price Change for the category:

	Other…	R1_1Salmon	R1_2Cod	PC1_1Salmon	PC1_2Cod	PC1_0Finfish

2015	…	0.0540541	0.9459459	0.0134715	0.0445941	0.0580655
2016	…	0.0532544	0.9467456	-0.0274080	-0.0024612	-0.0298692

2.0.11 Price Index for the each category (PI_t)

We calculate the price index first by comparing by multiplying the previous years PI_{t-1} by that year's price change PC_t, where the PI of the first year $PI_{t=firstyear} = 1$

$$PI_t = PI_{t-1} * \exp(ln(\frac{P_{i,t}}{P_{i,t-1}})) = PI_{t-1} * \exp(PC_t)$$

Where

$$PI_{i,t_{firstyear}} = 1$$

```
#Note that the first row of this column is = 1
tempPI1<-data.frame(c(1, rep_len(x = NA, length.out = nrow(temp)-1)))
rownames(tempPI1)<-rownames(temp)

PC0<-temp[,names(temp) %in% paste0("PC", NameBasecategory)] #this is equal to ln(P_it/P_it-1)

  # Calculate
for (t in 2:nrow(tempPI1)){  #Since the first row is defined, we need to start at the second row
    tempPI1[t,1]<-tempPI1[t-1,1]*exp(PC0[t])
}
```

Then, to change the price index into base year dollars, we use the following equation:

$$PI_t = PI_t / PI_{t=baseyear}$$

In this example, our base year is 2010. Notice that the $PI_{i,t=baseyr} = 1$

```
tempPI2<-tempPI1[,1]/tempPI1[rownames(tempPI1) %in% baseyr,1]
```

	tempPI1	tempPI2
2007	1.0000000	1.160864
2008	1.0145060	1.177703
2009	1.0344514	1.200857
2010	0.8614275	1.000000
2011	0.9456527	1.097774
2012	0.9323310	1.082309
2013	1.0445909	1.212628
2014	1.0351767	1.201699
2015	1.0970642	1.273542
2016	1.0647803	1.236065

In the future, we will use this *PriceIndex* function to do this step:

```
print(PriceIndex)
```

```
## function(temp, BaseColName, baseyr) {
##   ###Price Index for the entire commercial fishery ($PI_t$)
##
##   # We calculate the price index first by comparing by multiplying the previous years $PI_{t-1}$ by t
##   # $$PI_t = PI_{t-1}*exp(ln(\frac{P_{i,t}}{P_{i,t-1}})) = PI_{t-1}*exp(PC_{t})$$
##   # Where
```

```
##   # $$PI_{i, t_{first year}} = 1$$
##
##   #Note that the first row of this column is = 1
##   tempPI1<-c(1, rep_len(x = NA, length.out = nrow(temp)-1))
##
##   PC0<-temp[,names(temp) %in% paste0("PC", BaseColName)] #this is equal to ln(P_it/P_it-1)
##
##   # Calculate
##   for (t in 2:length(tempPI1)){  #Since the first row is defined, we need to start at the second row
##     tempPI1[t]<-tempPI1[t-1]*exp(PC0[t])
##   }
##
##   tempPI1<-data.frame(tempPI1)
##   rownames(tempPI1)<-rownames(temp)
##
##   # Then, to change the price (calulated later) into base year dollars, we use the following equation
##   # $$PI_{t} = PI_{t}/PI_{t = baseyear}$$
##   # In this example, we'll decide that the base year is `r baseyr`, for whatever reason. Notice that
##
##   tempPI2<-tempPI1/tempPI1[rownames(tempPI1) %in% baseyr,]
##
##   tempPI<-data.frame(tempPI2)
##   names(tempPI)<-paste0("PI", BaseColName)
##
##   return(tempPI)
## }
```

And we add the PI to the data

```
tempPI<-PriceIndex(temp, BaseColName = NameBasecategory, baseyr)
temp[ncol(temp)+1]<-(tempPI)
names(temp)[ncol(temp)]<-paste0("PI", NameBasecategory)
```

	PI1_0Finfish

Is there a warning?

No warning.

2.1 Redo Analysis for Shellfish

Now lets redo that whole analysis up to this point (via function) for the two species of the shellfish group, as we will need them for the next steps of this analysis.

We use this *species.cat.level* function to calculate the Implicit Quanity Output at Species and category Level:

```
print(species.cat.level)
```

```
## function(temp, ii, baseyr, maxyr, minyr, PercentMissingThreshold, warnings.list) {
##
##   ########Housekeeping
##   # Here I am just going to collect some housekeeping items
##   temp<-data.frame(temp)
##
##   NumberOfSpecies<-numbers0(x = c(0, strsplit(x =
##                                                  strsplit(x = names(temp)[1],
##                                                           split = "_")[[1]][2],
##                                                split = "[a-zA-Z]")[[1]][1]))[1]
##
##   NameBaseTotal<-substr(x = names(temp)[grep(x = names(temp), pattern = paste0(NumberOfSpecies, "Tota
##                         start = 2,
##                         stop = nchar(names(temp)[grep(x = names(temp),

2.1.1 Value for all fisheries for species where P was able to be calculated

$R_{i,t}$, defined and discussed in the subsequent step, will need to sum to 1 across all species in a category. Therefore, you will need to sum a new total of $V_{i,t}$ (called VV_t) for the category using only values for species that were used to calculate $PI_{i,t}$.

$$VV_t = \sum_{s=1}^{n}(VV_{i,t})$$

where:

- VV_t is the new total of $V_{i,t}$ for the entire fishery using only values for species that were used to calculate $P_{i,t}$

VV1	_0Finfish VV2	_0Shellfish VV0	_0Total
2007	2900	1800	4700
2008	2800	2200	5000
2009	3000	1800	4800
2010	3100	1600	4700
2011	3200	1800	5000

2015	3700	2000	5700
2016	3380	2300	5680

2.1.2 Revenue Share for the entire commercial fishery (R_t)

$$R_{i,t} = V_{i,t}/V_t$$

where:

- $R_{i,t}$ is the revenue share per individual species (s), category (i), for each year (t)
- $V_{i,t}$ is the value ($) per individual species (s), category (i), for each year (t)

Here, we don't use VV_t beacause we want to expand the proportion to include all of the species caught, regardless if they were used in the price calculations.

```
names(temp)[names(temp) %in% paste0("V", NameBaseTotal)]<-paste0("REMOVED_V", NameBaseTotal)

temp0<-temp[grep(x = names(temp),
                 pattern = paste0("V[1-9]+_", NumberOfSpecies))]
temp0<-temp0[,-(grep(x = names(temp0), pattern = c("VV")))]
temp0<-temp0[,-(grep(x = names(temp0), pattern = c("REMOVED_")))]

temp[ncol(temp)+1]<-rowSums(temp0, na.rm = T)
names(temp)[ncol(temp)]<-paste0("V", NameBaseTotal)

#remove duplicates
  temp<-temp[, !(grepl(pattern = "\\.[0-9]+", x = names(temp)))]

2.1.2.1 Analysis Warnings Checks

As an additional check, let's make sure that each row sums to 1.

	x
2007	1
2008	1
2009	1
2010	1
2011	1
2012	1
2013	1
2014	1
2015	1
2016	1

Is there a warning?

No warning.

2.1.3 Price Changes for the entire commercial fishery (PC_t)

Measure output price changes (PC_t) for total output (Q_t) using $R_{i,t}$ and $P_{i,t}$ estimates.

$$PC_t = ln(\frac{P_t}{P_{t-1}}) = \sum_{i=1}^{n}([\frac{R_{i,t} + R_{i,t-1}}{2}] * [ln(P_{i,t}) - ln(P_{i,t-1})])$$

```r
temp$PC0_0Total<-rowSums(cbind(PriceChange(R0 = temp$R1_0Finfish, P0 = temp$PI1_0Finfish),
                               PriceChange(R0 = temp$R2_0Shellfish, P0 = temp$PI2_0Shellfish)),
                         na.rm = T)
```

Warning: When back calculated, ln(Q_t/Q_{t-1}) = did not equal sum(((R_{i, t} - R_{i, t-1})(2)) ln((Q_{i,t})(Q_{i,t-1}))*

2.2.0.4 4. Missing Data

FYI: Out of 5 columns, 0 of species V columns are completely empty, 1 of species Q columns are completely empty, and 0 of 5 species P columns are completely empty.

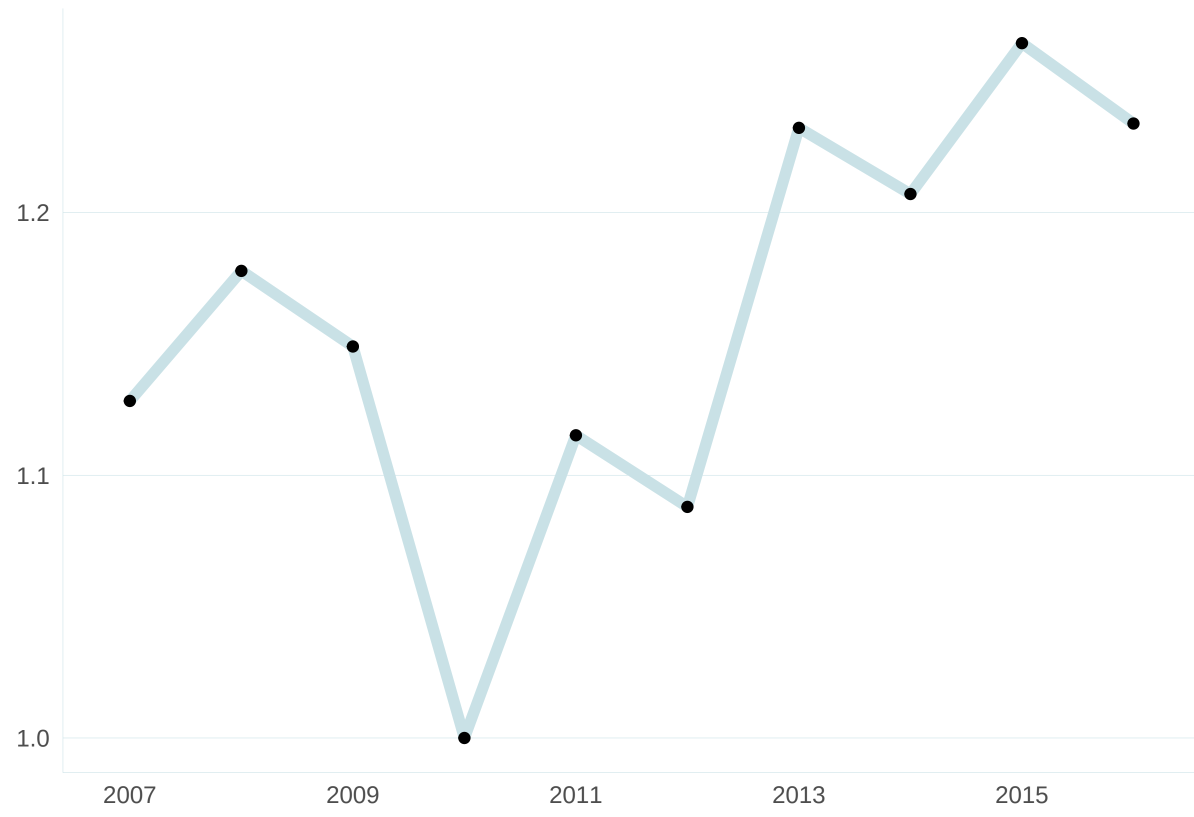
2.2.0.5 5. Removed Data

FYI: Out of 6 columns, 1 of species V columns were removed, 1 of species Q columns were removed, and 0 of 6 species P columns were removed.

2.2.1 Graph 1: Price Index

In theory, PI should be negative slope after the baseyear and positive after the base year, but because this data was fabricated without thinking of this, we don't see that here. The index value for the base year is = 1, however.

```
# A function I made to plot this pretty in ggplot2
temp <- temp[, !duplicated(colnames(temp))]
plot1line(temp, PI = temp$PI0_0Total,
            NOAALightBlue, NOAADarkBlue, NOAADarkGrey)
```



2.2.2 Graph 2: Quantity Index Compare

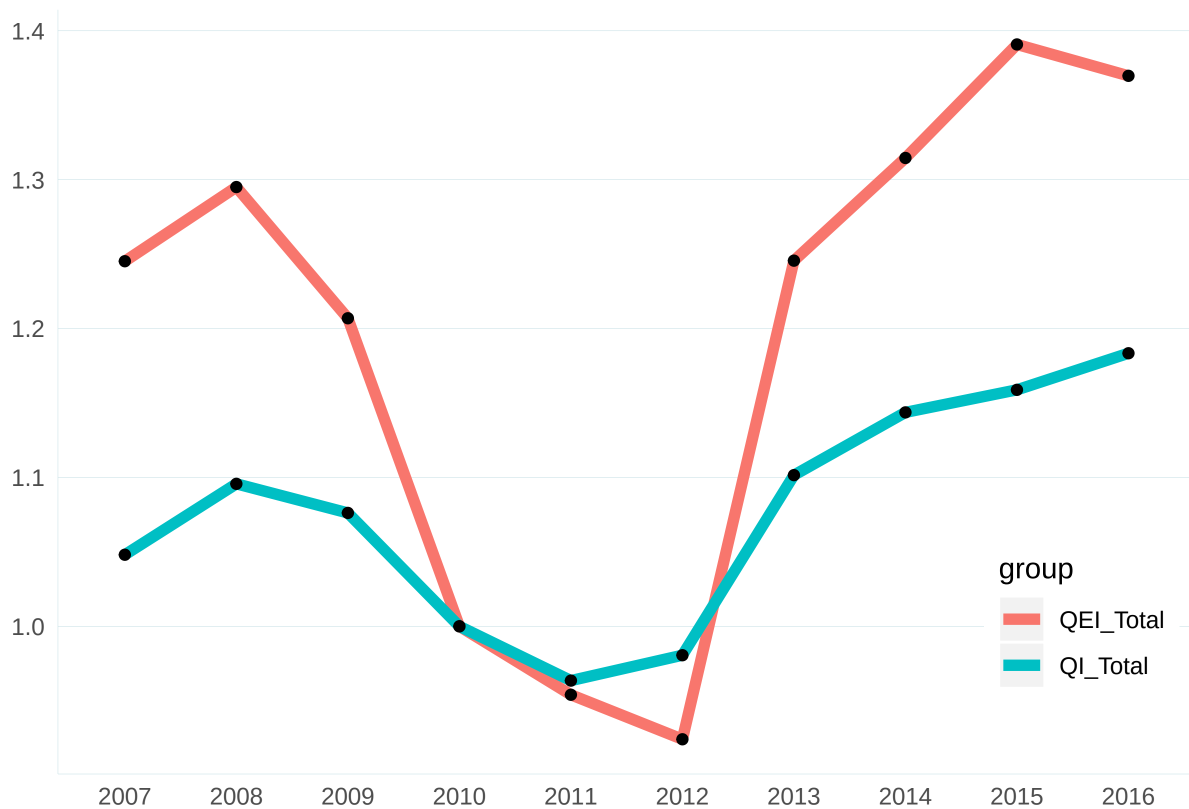
```
temp0<-temp
temp0$Year<-rownames(temp0)
```

```
tempA<-data.frame(temp0[,names(temp0) %in% c("Year", "QI0_0Total")])
names(tempA)<-c("Index", "Year")
tempA$group<-"QI_Total"
tempA$col<-NOAALightBlue

tempB<-data.frame(temp0[,names(temp0) %in% c("Year", "QEI0_0Total")])
names(tempB)<-c("Index", "Year")
tempB$group<-"QEI_Total"
tempB$col<-NOAADarkBlue

temp0<-rbind.data.frame(tempA, tempB)
rownames(temp0)<-NULL
temp0$col<-as.factor(temp0$col)

#A function I made to plot this pretty in ggplot2
plot2line(temp0, Year = temp0$Year, Index=temp0$Index, col = temp0$col, group = temp0$group,
                    NOAALightBlue, NOAADarkBlue, NOAADarkGrey)
```



2.2.3 Graph 3: Quantity Compare

```
temp0<-temp
temp0$Year<-rownames(temp0)

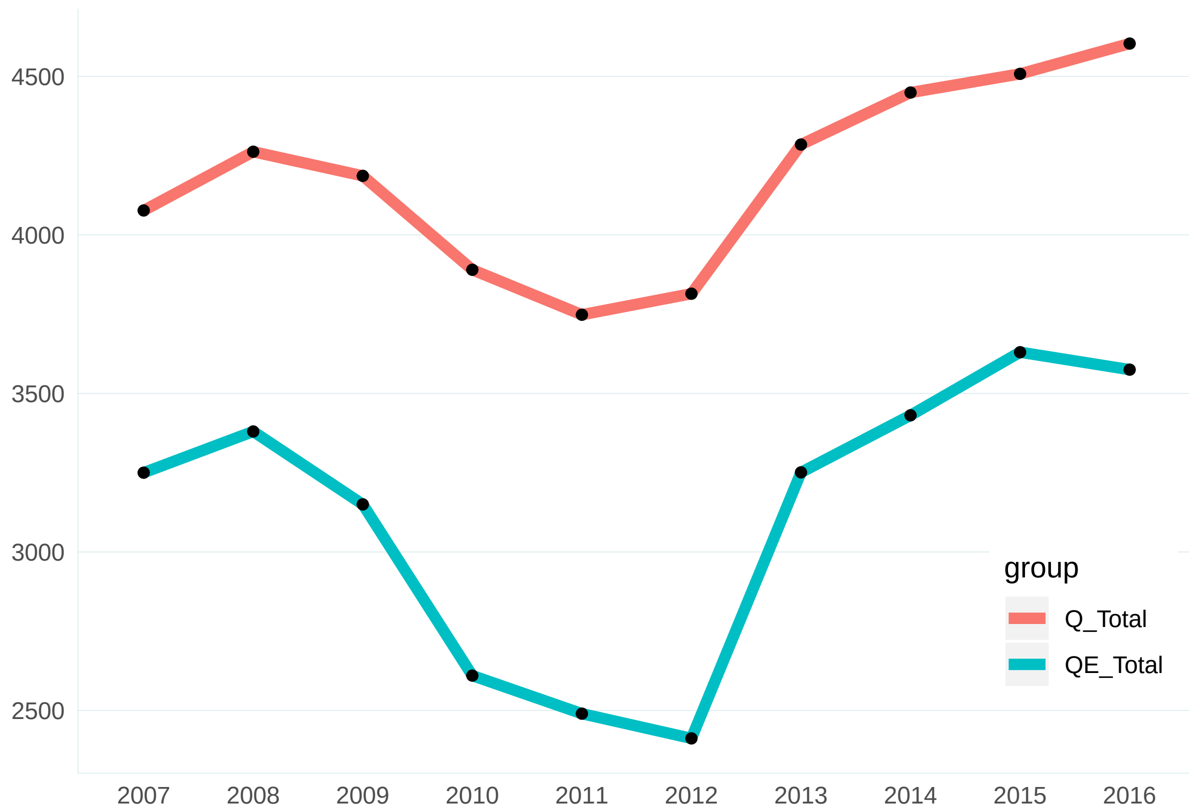
tempA<-data.frame(temp0[,names(temp0) %in% c("Year", "Q0_0Total")])
```

```
names(tempA)<-c("Quantity", "Year")
tempA$group<-"Q_Total"
tempA$col<-NOAALightBlue

tempB<-data.frame(temp0[,names(temp0) %in% c("Year", "QE0_0Total")])
names(tempB)<-c("Quantity", "Year")
tempB$group<-"QE_Total"
tempB$col<-NOAADarkBlue

temp0<-rbind.data.frame(tempA, tempB)
rownames(temp0)<-NULL
temp0$col<-as.factor(temp0$col)

#A function I made to plot this pretty in ggplot2
plot2line(temp0, Year = temp0$Year, Index=temp0$Quantity, col = temp0$col, group = temp0$group,
                    NOAALightBlue, NOAADarkBlue, NOAADarkGrey)
```



2.3 Do same analysis via a function!

Now that we know the method, we can simplify most of it into a function and do this whole analysis in 4 easy steps:

- A. Import and Edit data
- B. Enter base year

- C. Run the function
- D. Obtain the implicit quantity estimates

2.3.1 Function

We use this *ImplicitQuantityOutput* function to calculate the Implicit Quanity Output at Fishery Level:

```
print(ImplicitQuantityOutput)
```

```
## function(temp, baseyr, calcQEI = F, PercentMissingThreshold = 1.00, title0 = "", place = ""){
##
##   temp.orig<-temp
##
##   warnings.list<-list()
##   figures.list<-list()
##

##   return(list(temp, warnings.list, figures.list))
## }
```

2.3.2 A. Import and Edit data

```
temp<-read.csv(file = paste0(dir.data, "Tornqvist Index-Calculations_OutputEx.csv"))
rownames(temp)<-temp$year
temp$year<-NULL

temp.q<-temp[,grepl(pattern = "Q", x = names(temp))]
temp.q$QE0_0Total<-rowSums(temp.q, na.rm = T)
temp.q$QE1_0Finfish<-rowSums(temp.q[,grepl(x = names(temp.q), pattern = "Q1") ], na.rm = T)
temp.q$QE2_0Shellfish<-rowSums(temp.q[,grepl(x = names(temp.q), pattern = "Q2") ], na.rm = T)
```

```
temp.v<-temp[,grepl(pattern = "V", x = names(temp))]
temp.v$V0_0Total<-rowSums(temp.v, na.rm = T)
temp.v$V1_0Finfish<-rowSums(temp.v[,grepl(x = names(temp.v), pattern = "V1") ], na.rm = T)
temp.v$V2_0Shellfish<-rowSums(temp.v[,grepl(x = names(temp.v), pattern = "V2") ], na.rm = T)

temp<-orgional.data<-cbind.data.frame(temp.q, temp.v)
```

2.3.3 B. Enter base year

```
baseyr<-baseyr
```

2.3.4 C. Run the function

```
temp00<-ImplicitQuantityOutput(orgional.data, baseyr, calcQEI = T, PercentMissingThreshold)
temp<-temp00[[1]]
warnings.list0<-temp00[[2]]
figures.list0<-temp00[[3]]
```

2.3.5 D. Obtain the implicit quantity estimates

Did all of the analyses work as intended?

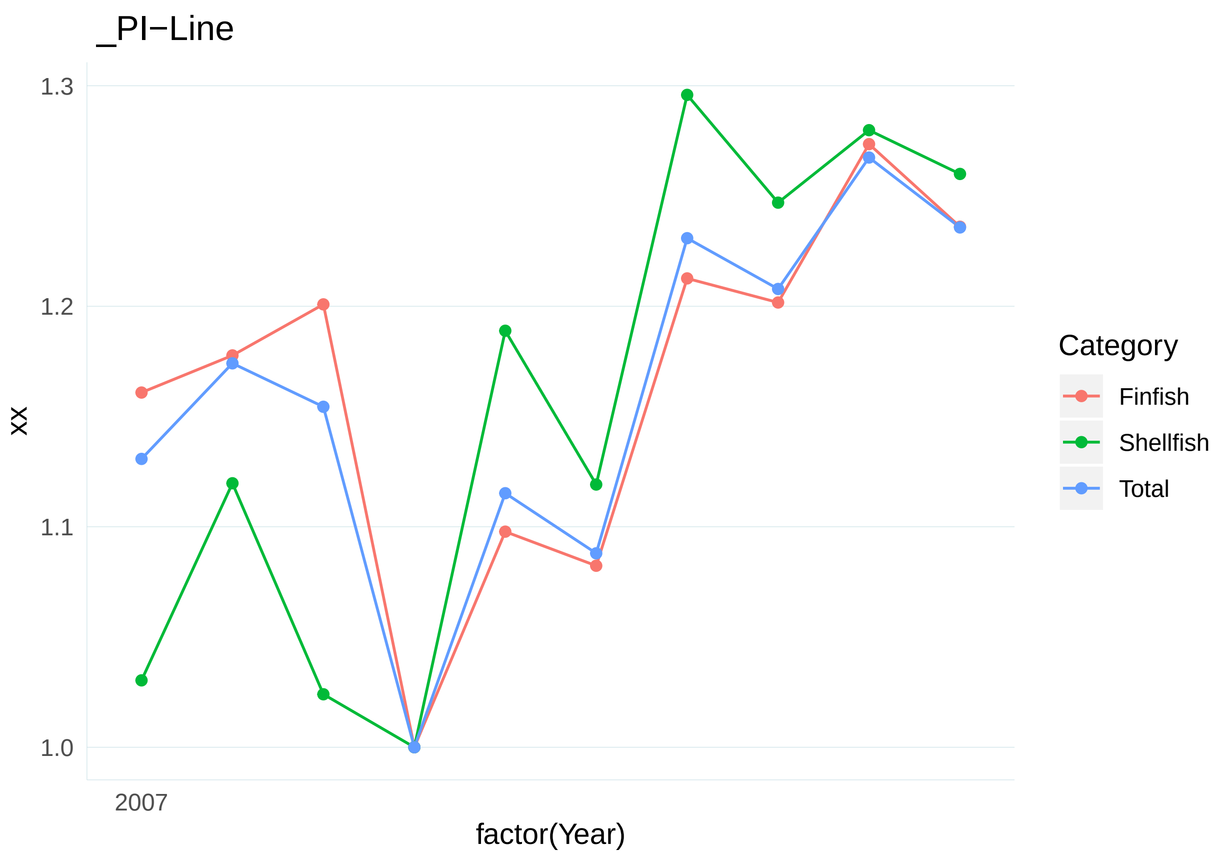
Warning: When back calculated, ln(Q_t/Q_{t-1}) = did not equal sum((R_{i, t} - R_{i, t-1}) / 2) x ln((Q_{i,t}) / (Q_{i,t-1})), FYI: Out of 6 columns, 0 of species V columns are completely empty, 1 of species Q columns are completely empty, and 1 of 6 species P columns are completely empty.

2.3.6 E. Graph

2.3.6.1 Graph 1: Price Index

For comparison, let's recreate those graphs to make sure we are getting the same output:

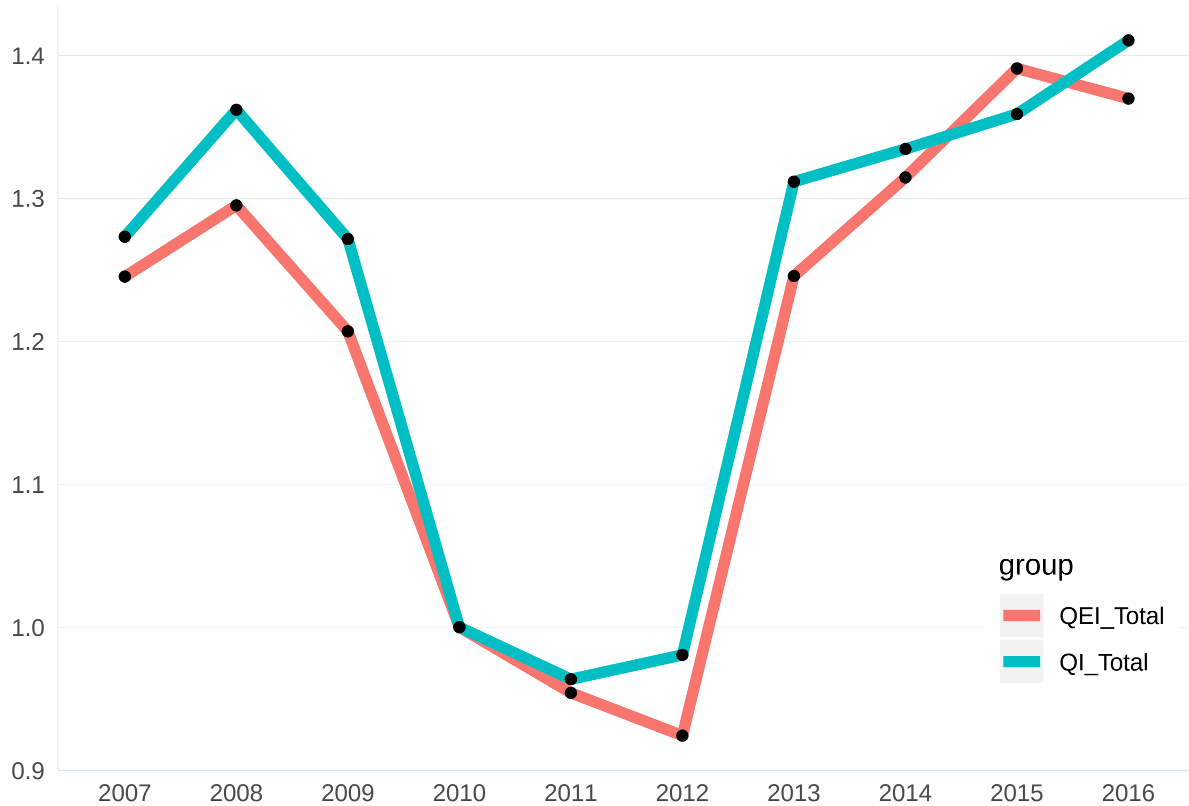
```
figures.list0$`_PI-Line`
```



2.3.6.2 Graph 2: Quantity Index Compare

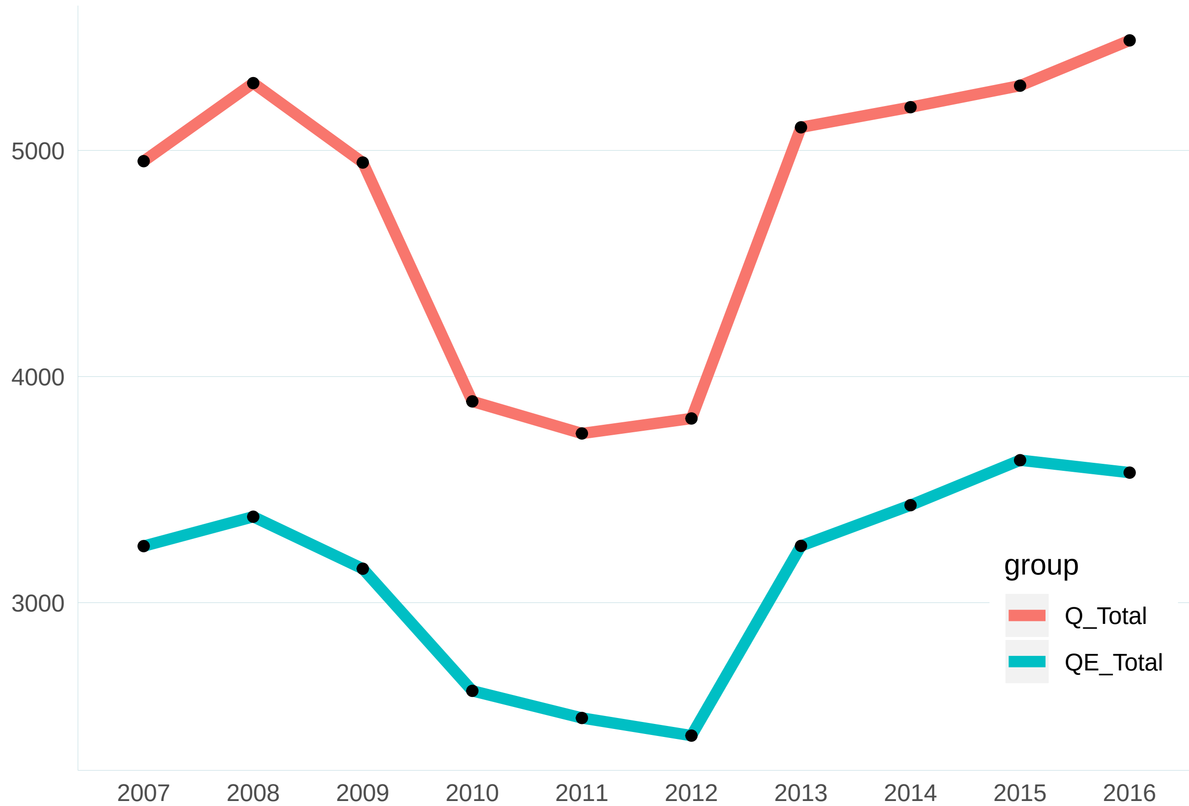
For comparison, let's recreate those graphs to make sure we are getting the same output:

```
figures.list0$`_QuantityIndexCompare`
```



2.3.6.3 Graph 3: Quantity Compare

```
figures.list0$`_QuantityCompare`
```



2.4 Practice with real data (For National Data)

2.4.1 A. Import and Edit data

Load and subset Data

```
#Load Data (This data has been edited to include category columns)
landings.data<-read.csv(file = paste0(dir.data, "landings_edited.csv"))
landings.data<-landings.data[landings.data$Year < 2018,] #FUS 2018 hasn't been published yet
landings.data<-landings.data[landings.data$State %in% unique(state.codes$NAME),]
region<-"National"
#We'll categorize by this column I already added to the data
category0 = "category.orig"
```

Summary information about the commercial dataset:

Did all of the analyses work as intended?

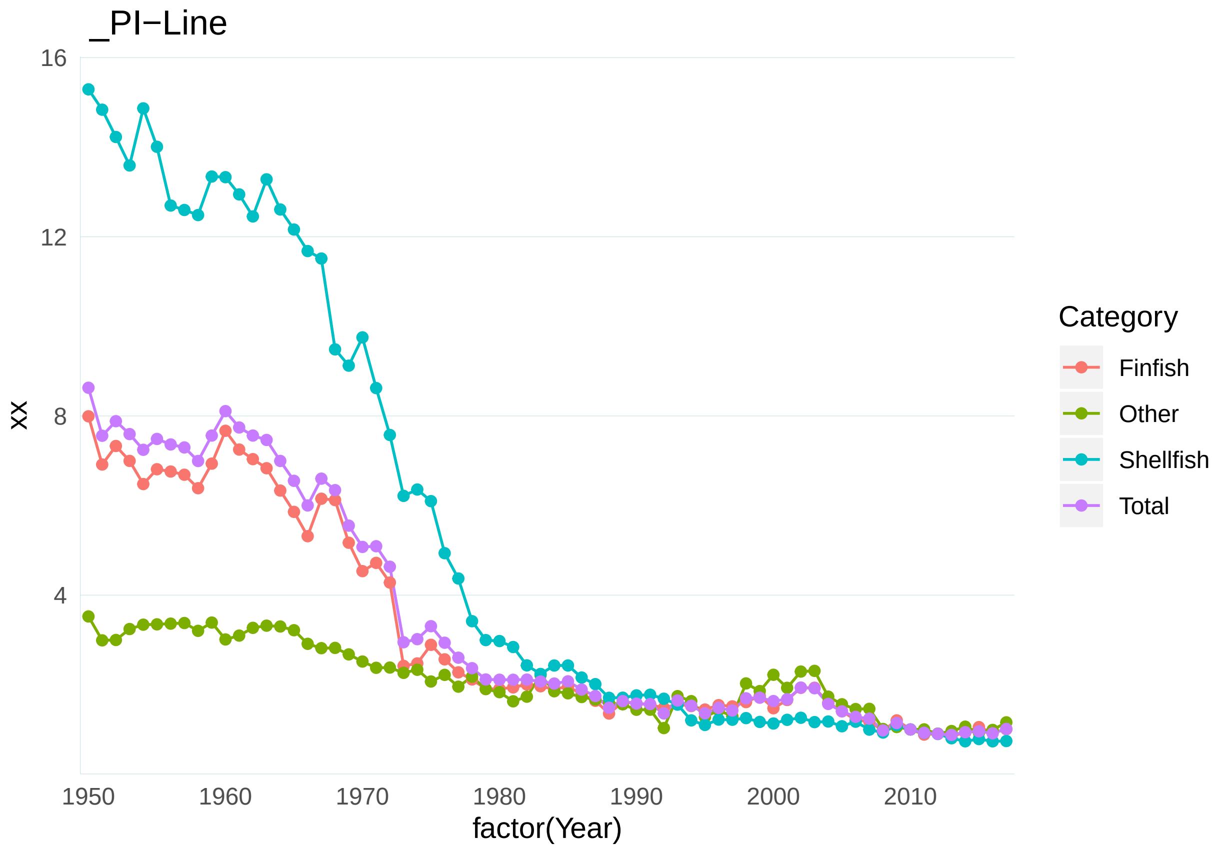
Warning: When back calculated, ln(Q_t/Q_{t-1}) = did not equal sum((R_{i, t} - R_{i, t-1}) / 2) x ln((Q_{i,t}) / (Q_{i,t-1})), FYI: Out of 30 columns, 32 of species V columns are completely empty, 34 of species Q columns are completely empty, and 0 of 30 species P columns are completely empty.

2.4.5 E. Graph

2.4.5.1 Graph 1: Price Index

For comparison, let's recreate those graphs to make sure we are getting the same output:

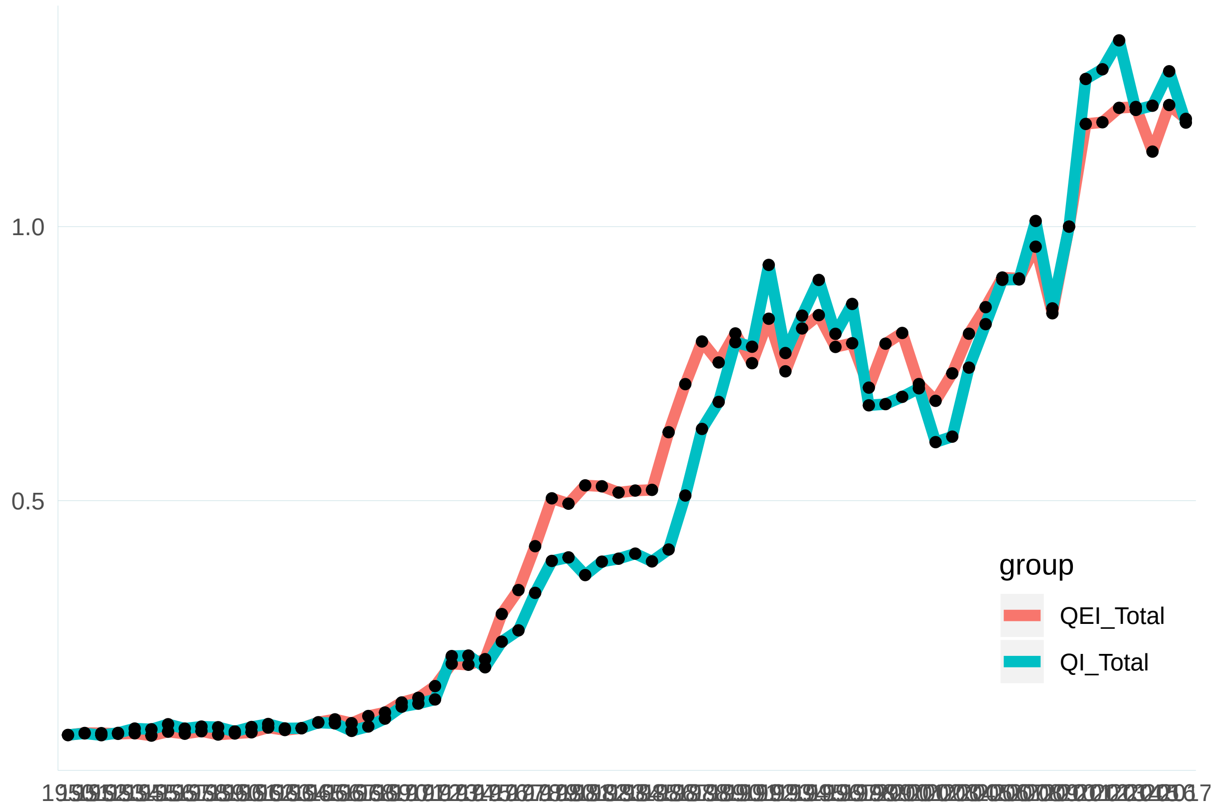
```
figures.list0$`_PI-Line`
```



2.4.5.2 Graph 2: Quantity Index Compare

For comparison, let's recreate those graphs to make sure we are getting the same output:

```
figures.list0$`_QuantityIndexCompare`
```



2.4.5.3 Graph 3: Quantity Compare

```
figures.list0$`_QuantityCompare`
```
